#### Abstract

Face Recognition System employs a variety of feature extraction (projection) techniques which are grouped into Appearance-Based and Feature-Based. In a vast majority of the studies undertaken in the field of Face Recognition special attention is given to the Appearance-Based Methods which represent the dominant and most popular feature extraction technique used. Even though a number of comparative studies exist, researchers have not reached consensus within the scientific community regarding the relative ranking of the efficiency of the appearance-based methods (LDA, PCA etc) for face recognition task.

This paper studied two appearance-based methods (LDA, PCA) separately with three (3) distance metrics (similarity measures) such as Euclidean distance, City Block \& Cosine to ascertain which projection-metric combination was relatively more efficient in terms of time it takes to recognise a face. The study considered the effect of varying the image data size in a training database on all the projection-metric methods implemented. LDA-Cosine Distance Metric was consequently ascertained to be the most efficient when tested with two separate standard databases (AT \& T Face Database and Indian Face Database). It was also concluded that LDA outperformed PCA.

## ACKNOWLEDGEMENT

My heartfelt gratitude is first and foremost expressed to the Almighty God for giving me wisdom, knowledge, understanding and strength to undertake and accomplish this research work.

I owe God much appreciation for his immense providence and I dedicate this thesis to Him. Secondly, I extend my profound and sincere gratitude to my supervisor, Dr. Asante who availed himself despite his busy schedule to have fruitful meetings with me to completion of this work. I am also equally indebted to the numerous authors whose books, journals were used as references in my bid to have the project work completed.

My special thanks also go to my family particularly my lovely wife Mrs Rose Abena Peprah and my children for their support and encouragement to the completion of this masters program.

Again, to AT \& T Laboratories at Cambridge and Indian Institute of Technology, Kanpur I am very much grateful for making public their standard face image database for me also to use for my experiments. And finally I extend my gratitude to Mr Amir Hossein Omidvarmia, whose MATLAB sample codes on the Internet greatly helped me in my work.

## DEDICATION

This is dedicated to God, my source of livelihood, and my family particularly my lovely wife Mrs Rose Abena Peprah and my children for their immense support and encouragement.

## CHAPTER ONE

## INTRODUCTION

Face recognition has been one of the most relevant applications of image analysis. It is challenged to build an automated system which has the ability to recognise faces as human beings. In spite of the fact that human beings are quite good at identifying known faces, we are limited when we have to deal with large amount of unknown faces. Computers, with an almost limitless memory and computational speed should overcome human limitations. It is therefore not surprising that computer-based face recognition has been an active research area over three decades. For instance a lot of scientists from different branches have delved into this area.

The term face recognition can be referred to as classifying or identifying, by computational algorithm, an unknown face image. This operation compares the unknown face image with the known face images stored in a database.

The input of a face recognition system is always an image or video stream. The output is an identification or verification of the subject or subjects that appear in the image or video.

Facial identification consists of assigning input face image to one person of a known group.
Facial verification consists of validating the previously detected person's identity.
Figure 1-1 indicate the generic representation of face recognition system

Figure 1-1: Generic Face Recognition System

There are a number of techniques that Face recognition systems can employ for feature extraction.

Generally face recognition techniques can be divided into two groups based on the face representation they use:
i. Appearance-based: With this method, the entire face image is used to derive the most important information that describes a face best. Principal component analysis, Linear discriminant analysis, Independent component analysis are a few examples of appearancebased methods.
ii. Feature-based: This method uses geometric facial features (mouth, eyes, brows, cheeks etc) and geometric relationships between them. It is based on extracting feature vectors from the basic parts of a face such as eyes, nose, mouth, and chin.

A great number of studies in face recognition had paid special attention to the appearance based methods, which has been the most popular feature extraction techniques used in the field of face recognition. Often time researchers reported contradictory results concerning the relative performance of the appearance based techniques. Thus, no consent has been reached within the scientific community regarding the relative ranking of the efficiency of appearance based methods for the face recognition task.

### 1.1 Problem Statement

In spite of the number of comparative studies that have been done on the topic understudied very often a contest between the abilities of the research groups rather than a comparison between methods was performed. Again, not all possible implementations were considered. Often times other studies had focused on the feature extraction techniques of face recognition (projection methods). That is, the projection methods (such as PCA, LDA etc ) were seldom combined with a number of similarity criteria to determine which projection-metric combination was relatively
efficient.In most cases only one similarity measure (distance metric) was combined with the projection methods and in some cases using nonstandard databases.

More often than not, where more than one distance metric classifiers were used variability of data size and its effect on their results were not considered. In the case where variability of data size was considered one distance metric classifier (i.e. Euclidean distance most commonly used) was used. This study considered more than one distance metric classifiers and the variability of data size.

Again the findings of other research groups were often contradictory on the subject as indicated earlier and that was another important reason for performing a study of this kind. Thus, the relative performance of the two techniques is an open question.

This thesis studied two appearance-based techniques combined with three distance metrics. Projection methods studied were: Principal Component Analysis (PCA), Linear Discriminant Analysis. The Similarity Matching Methods (Distance metrics) used were City Block, Euclidean, and Cosine Metrics.

### 1.2 Objective

The thesis aimed at studying and ascertaining which projection-metric combination was more efficient using MATLAB. Specifically the objectives were as follow:

- To study and understand the two appearance-based methods i.e. PCA and LDA as applied in face recognition.
- To study and understand the three similarity measures (distance metrics) i.e. Euclidean distance, City Block and Cosine as applied in face recognition
- To combine each of the projection method with each similarity measure.
- To design and implement algorithm of each projection-metric method with varying data
size.
- To analyze the results and report the most efficient among the combined projectionmetric methods.

### 1.3 Methodology

The methodology of this thesis was based upon information gathered and processed during the study and research phase of the course. The method applied for the design and implementation of the face recognition system was as follows:

Data Formation phase: This phase involved the acquisition of face images from standard face image database through the Internet and the pre-processing of such images using MATLAB. The pre-processed images were stored into Training database.

Training Phase: In this phase, those face images used in the training set were chosen from the entire training database. After obtaining the training set (consisting of converted vectors of the face images), feature vectors (eigenfaces or fisherfaces)were formed by applying the appearancebased techniques (feature extraction technique) employed in this study i.e. PCA and LDA and stored for later use.

Recognition Phase: Having obtained feature vectors, recognition process began in this phase. At this stage, probe /test image was selected and used as input image to initiate the recognition process. Here determination was made whether input image was similar to any of the images (or has a match) in the training set using the similarity measure.

Similarity Matching Methods: They define a value that allows the comparison of feature vectors of test image and those from the training set. This helps to find equivalent match in the database
for an input(test) image.. In this study, similarity matching methods employed were Euclidean and City Block distance, and Cosine distance.

Performance evaluation phase: This phase showed the comparative analysis of the outcome of face recognition techniques employed. This was based on the accuracy (number of correct match), time of execution of algorithm. The generalization ability of the combined projectionmetric methods was also ascertained.

The generalization ability of an algorithm has several meanings some of which are; It is an ability to maintain a recognition rate when reducing the number of images in the training set. Alternatively, when considering the algorithms that use more than one image per class in the training database, the ability of an algorithm to maintain a recognition rate when the number of images per class used in training is reduced (Navarrete and Ruiz-del-Solar, 2002).

### 1.4 Some applications of face recognition

Face recognition has been applied in many areas such as Law enforcement, Airport Secuirty, Access Control and Driver's Licences and Passport etc to help in the following;

- to help governments to stay ahead of the world's ever-advancing terrorists,
- To enhance security efforts that already underway at most airports and other major transportation hubs (seaports, train stations, etc.),
- To enhance security efforts considerably in organisations,
- To leverage the existing identification infrastructures in driver's licence and passport.

### 1.5 Research Questions

Which projection-metric combination algorithm yields higher recognition rate (accuracy)? Which projection-metric combination algorithm is more efficient in terms of time taken to recognise a face?

Does the varying of the number of training image affect the performance of projection metric algorithm?

What will be the effect of varying the number of training images in a class on projection-metric algorithm?

### 1.6 Significance of the study

This study seeks to deepen the search for most efficient and accurate technique for a face recognition system. Again, to determine which projection-metric can withstand increased data size of face recognition system. This, as a result, will help to design a face recognition system for Voter Registration and Verification, Driver's Licenses, Immigration activities and host of others which deals with large data and requires little amount of time to identify or verify ones image.

### 1.7 Organization of the Study

The study is organized into five chapters.

* Chapter One:The Chapter presents the Research Proposal, comprising of Introduction to the study, the Problem Statement, Objectives of the Study, Methodology, Some application of Face Recognition, Challenges to Face Recognition, Research Questions and Significance of the study.
* Chapter Two: This presents a comprehensive review of relevant literature in order to position the study in an appropriate theoretical framework. Thus it deals with historical facts about Face Recognition, related works of the study and some findings, and theoretical framework of the two techniques under review.
* Chapter Three: This chapter also discusses the methodology employed for the study coupled with the algorithms of the two techniques and the standard face image database used. It also presents the results of the experiments undertaken in this thesis.
* Chapter Four: This chapter analyses results of the experiments implemented.
* Chapter Five: This chapter presents conclusion for the study and future work.

## CHPATER TWO

## LITERATURE REVIEW

### 2.1 History of Face Recognition

Studies in the field of face recognition dated back to $19^{\text {th }}$ century where Darwin (1872) worked on different facial expression due to different emotional state, and Galton (1888) worked on facial profile. Thereafter, there were some attempts to develop semi-automated facial recognition system in the late 1960s and early 1970s based on geometrical information(such as eyes, nose mouth etc and their geometric relationship). For instance, Goldstein et al (1971) created a system of 21 subjective marks such as hair colour and lip thickness but was very difficult to automate. Fischler and Elschanger(1973) measured the facial features using templates of single facial features and mapped onto global template. However, Kenade (1973) developed the first fully automated face recognition system, whose algorithm extracted 16 facial parameters automatically and compared to human or manual extraction which showed only small difference. From the above historical facts, it is obvious that early part of face recognition focused on automatic detection of individual facial features. This approach had advantages of being insensitive to illumination and that there was intuitive understanding of the extracted features. However, according to Cox et al (1996), and Li and Jain (2005)facial feature detection and measurement techniques were not reliable enough for the geometric feature-based recognition of a face and geometric properties alone were inadequate for face recognition. As a result of this setback geometric feature-based technique had gradually been abandoned and an effort had been made in researching holistic (appearance-based) techniques, which provided better results.

Sirovich and Kirby (1987) were the first to employ Eigenface technique which was based on
PCA to recognise an image in a lower dimension without losing much information and then reconstructing it. Turk and Pentland (1991) enhanced this coarse method.

Since the 1990s, face recognition has received a lot of attention with a noticeable increase in a number of publications resulting in other holistic techniques like Fisher Discriminant Analsys, Independent component Analysis etc.

### 2.2 RELATED WORKS

As shown in the figure 1-1 feature extraction techniques plays important role in every face recognition system particularly on the performance of such systems. It is therefore imperative to have a detailed knowledge of the extraction techniques employed for effective design of recognition schemes and then for construction of robust face recognition systems. A lot of studies have been conducted by Researchers to compare various feature extraction techniques and their robustness to facial appearance changes. Most of these studies paid special attention to appearancebased methods, which were the most popular feature extraction techniques used in the field of face recognition.

However, more often than not researchers reported contradictory result of the comparative studies conducted with respect to the performance of the appearance-based techniques. For example, Beveridge et al(2001) reported that in their experiments PCA systematically outperformed LDA, whereas Belhumeur et al (1997) claimed that LDA performs better than PCA in all of their tests. According to Delac et al (2006) the performance of the appearancebased techniques largely depended on the similarity measure employed. As result, with the right combination of the technique and distance no claim regarding the superiority of any of the three techniques i.e., PCA, LDA, ICA, could be made.

It is quite obvious from the discussion that even within the scientific community different results had been found regarding the relative ranking of the appearance-based methods for the face recognition task.

### 2.3FINDINGS

Having studied literature and journals on face recognition it was observed that appearancebased image approaches seemed to dominate up to now in face recognition systems mainly because of the strong prior knowledge that all face images belong to face class.

Again, it is important to note that some differences and similarities between PCA and LDA were found. PCA tries to keep as much structure of the features (variance). It de-correlates the feature space and orders the dimension with decreasing variance. In order to reduce dimensionality and choose the first N dimension the most structure of the data is kept.LDA rather focus on dimension that separates classes and orders dimension according to class separability. LDA explicitly attempts to model the difference between classes of data whereas PCA on the other hand does not take into account any difference in class. Whereas LDA seeks directions that are efficient for discriminating data, PCA seeks the directions that are efficient for representing data. There are some characteristics which are common to both PCA and LDA. First and foremost, they produce spatially global feature vectors. In other words, they produce basis vectors which are non-zero for almost all dimensions. This implies that a change to a single input pixel will change every dimension of its subspace projection. Again, they both look for linear combinations of variables which best explain the data.

Database: At the early stage of face recognition every individual or research group collected their own database of images. Subsequently, it became necessary to have a uniform benchmark database and thus FERET database was collected at NIST (National Institute of Standards and Technology), AT and T database at AT and T Laboratories Cambridge (2002), Indian Face Database at Indian Institute of Technology, Kanpur etc for testing face recognition algorithms. In this study,
the standard databases used were AT and T database and Indian Face Database for testing face recognition algorithms.

Another observation was that, the most commonly used parameters for face recognition were as follows:
i. Accuracy
ii. Variability in data size iii. Blurriness in test data
iv. Image size.

It is important to note , however that where more than one distance metric classifiers were used variability of data size and its effect on their results were not considered. In the case where variability of data size was considered one distance metric classifier (i.e. Euclidean distance most commonly used) was used.

However, this study considered more than one distance metric classifiers and the variability of data size.

### 2.4 FACE SPACE

Generally, a two dimensional image $I(x, y)$ of size $m$-by- $n$ pixels can be viewed as a vector (or a point) in high dimensional space, where $m$ is the number of rows of pixels and $n$, the number of columns of pixels.

An image space can be referred to as a space having dimensions equal to the number of pixels making up the image and having values in the range of the pixels values. Thus, for example with a grey scale image of size $(m \mathrm{x} n)$, the dimension of the image space is P , where $\mathrm{P}=\mathrm{m} \mathrm{x} \mathrm{n}$. In respect of gray scale images, the image could have a dimension with a value in between 0 and 255 .

A face image can be referred to as a point in the image space by converting the image to a long vector by concatenating each column of the image one after the other as illustrated in the Figure 2-1.

When all the face images are converted into vectors, they will group at a certain location in the image space as they have similar structure, having eyes, nose and mouth in common and their relative position correlated as illustrated in Figure 2-2.Therefore, all the face vectors are located in a very narrow cluster in the image space as face space.

Figure 2-2 Image Space and face cluster

### 2.5 Principle Component Analysis (PCA)

## Introduction

PCA is a standard technique used in statistical pattern recognition and signal processing for data reduction and Feature extraction. In this method, patterns are mapped onto feature vectors to remove redundant information which they normally contain while preserving most of their intrinsic information content. These extracted features play very important role when input patterns have to be distinguished.

It can also be described as a method of transforming a number of correlated variables into a smaller number of uncorrelated variables. PCA behaves in much the same way as Fourier analysis in that they both decompose signals into a set of additive orthogonal basis vector(in the case of PCA ) or sinusoids of varying frequencies (in the case of Fourier analysis). There is one important difference between them. That is whereas Fourier analysis uses a fixed set of basis function, the PCA basis vectors are learnt from the data set via unsupervised training.

## How PCA Works

PCA focuses on explaining the covariance structure of a set of variables. Particularly, it helps in identifying the principal directions in which the data varies.

Take for instance, two variable data set in the X-Y coordinate system as illustrated in figure 2-
3.The U axis and the V axis which are orthogonal to each other shows the principal direction in which the data varies. If the $U-V$ axis system is placed at the mean of the data it will give a compact representation. When each ( $\mathrm{X}, \mathrm{Y}$ ) coordinates is transformed into its corresponding ( U , V) value it will de-correlate the data. This means that the co-variance between the U and V variables becomes zero.

For a given set of data, PCA finds the axis system which is defined by the principal directions of variance (i.e. the $U-V$ axis system in figure 2-3). The directions $U$ and $V$ are called the principal components.

Figure 2-3: PCA for Data Representation Figure 2-4: PCA for Dimension Reduction In a situation where natural property or experimental error causes variation in dataset, such dataset maybe expected to be normally distributed. The nominal extent of the normal distribution is shown by hyper-ellipse in figure 2-3. This hyper -ellipse encloses data points that may be considered to belong to a class, hence it is thought of as class boundary.

Where some other relationship causes variation in data PCA will result in reducing the dimensionality of dataset. From figure 2-4 the two variables are nearly related linearly. From the figure2-3, the principal direction in which the data varies is shown by the $U$ axis and the secondary direction by the V axis. However, all the V coordinates are very close to zero. Assuming they are only non-zero because of experimental noise, then the U-V axis system can represent the data set with one variable U and discard V . Thus the dimensionality of the problem has been reduced by 1 .

## Computing the Principal Components

The principal components can be computed by calculating the eigenvectors and eigenvalues of the data covariance matrix ( $\sum$ ). Below is a standard technique to avoid computational complexities.

Let $\sum=\mathrm{X}=\mathrm{BB}^{\mathrm{T}}, \mathrm{n} \times \mathrm{n}$ matrix
Where B is nxp matrix, $\mathrm{n}>\mathrm{p}$
This covariance matrix is very hard to work with due to its huge dimension causing computational complexity.

To prove that the eigenvectors of $\mathrm{B}^{\mathrm{T}} \mathrm{B}(\mathrm{p} \times \mathrm{p})$ matrix can be used instead of $\mathrm{BB}^{\mathrm{T}}(\mathrm{nxn})$,
Let $Y=B^{T} B$ $\qquad$ (1) which is of size
( $\mathrm{p} \times \mathrm{p}$ ).

Then, the eigenvectors $\delta$ and the eigenvalues $\Lambda$ of Y are obtained as,

$$
\begin{equation*}
\mathrm{Y}_{\delta}=\Lambda \delta \tag{2}
\end{equation*}
$$

i.e $\quad B^{T} B_{\delta}=\Lambda \delta$

On left multiplying B both sides of (3),

BB т $\mathrm{B} \boldsymbol{\delta}=\mathrm{B} \Lambda \boldsymbol{\delta}$.

Since $\Lambda$ is a scalar, Equation (4) can also be written as

If $\mathrm{B}_{\delta}$ is substituted by $\mathrm{v}=\mathrm{B} \delta$ Then
$v=B \delta$.
is one of the eigenvectors of $\mathrm{X}=\mathrm{BB}^{\mathrm{T}}$ and its size is ( $\mathrm{n} x 1$ ).
It therefore implies that the eigenvectors of X can be deduced using the eigenvectors of Y . Hence a matrix of size ( $\mathrm{p} \times \mathrm{p}$ ) is utilized instead of a matrix of size ( $\mathrm{n} \times \mathrm{n}$ ). This formulation brings substantial computational efficiency.

From the figure 2-3 the matrix of eigenvectors $u$ will represent linear transformation, which transforms data points $[\mathrm{X}, \mathrm{Y}]$ axis systems into the $[\mathrm{U}, \mathrm{V}]$ axis systems. Generally, the linear transformation given by $v$ transforms the data points into a data set where the variables are uncorrelated. The correlation matrix of the data in the new coordinate system is $\Lambda$ which has zeros in all the off diagonal elements.

## PCA in practice

Figure 2-5: The PCA Transformation
Figure 2-5 gives a geometric illustration of the process in two dimensions. Using all the data points, the mean values of the variables $\left(\mu_{\times 1} ; \mu_{\times 2}\right)$ and the covariance matrix $\left(\sum\right)$ which is a $2 \times 2$ matrix in this case are found.

Calculating the eigenvectors of the co-variance matrix gives the direction vectors indicated by $\delta_{1}$, and $\delta_{2}$.Putting the two eigenvectors as columns in the matrix $\delta=\left[\delta_{1} \delta_{2}\right]$ creates a transformation matrix which takes the data points from the [x1; x2] axis system to the axis $\left[\delta_{1}, \delta_{2}\right]$ system with the equation:
$\mathrm{p}_{\delta}=\left(\mathrm{p}_{\mathrm{x}}-\mu_{\mathrm{x}}\right) . \delta$
where $\mathrm{p}_{\mathrm{x}}$ is any point in the $[\mathrm{x} 1 ; \mathrm{x} 2]$ axis system, $\mu_{\mathrm{x}}=\left(\mu_{\mathrm{x} 1} ; \mu_{\mathrm{x} 2}\right)$ is the data mean, and p is the coordinate of the point in the $\left[\delta 1 ; \delta_{2}\right]$ axis system.

## Dimension Reduction

PCA as dimension reducer can be explained by considering an application having M images with n pixels each. Then the entire data set can be written as an $\mathrm{n} \times \mathrm{M}$ data matrix E with each column of $E$ representing one image of the data set.

The standard technique is employed to reduce dimension to MxM matrix which would otherwise have been nxn matrix when computing covariance matrix of the dataset. This consequently results to M eigenvectors and their corresponding eigenvalues of the covariance matrix of data
set.
Size reduction can further be achieved by choosing to represent the data with fewer dimensions. Normally the set of $\mathrm{m}(\mathrm{m}<M<n)$ eigenvectors of the covariance matrix $\left(\sum\right)$ which have the m largest eigenvalues can be chosen. Typically for face recognition system m will be quite small. These can be composed in an $\mathrm{n} \times \mathrm{m}$ matrix $\delta \mathrm{pca}=\left[\delta_{1} ; \delta_{2} ; \delta_{3} \ldots \delta_{\mathrm{m}}\right]$ which performs the PCA projection. For any given image $p_{x}=\left(i_{1}, i_{2}, i_{3}, . . i_{n}\right)$ a corresponding point in the PCA space can be found by computing
$\mathrm{p}_{\delta}=\left(\mathrm{p}_{\mathrm{x}}-\mu_{\mathrm{x}}\right) \cdot \delta_{\mathrm{pca}}$
The m -dimension vector $\mathrm{p}_{\mathrm{\delta}}$ is all that is needed to represent the image. This is a massive reduction in data size since typically n will be at least 1600 and m varies between twenty and a few hundred proportionate to the number of training images. All the data base images can be stored in the PCA space and can easily search the data base to find the closest match to a test image.

PCA has an important feature of reconstructing original image from eigenfaces. This will require a computation of weight vector of each mean-centred image vector. Each weight vector of the face to be reconstructed is then multiplied by the selected eigenvectors. The result is added to mean
image vector to get an approximation of the original image .However, if all the eigenvectors are used then it is mostly to have the image as exactly as the original image..

Reconstructing any image with the inverse transform:
$\mathrm{px}=\mathrm{p}_{\delta .} \delta_{\mathrm{pca}}^{\mathrm{T}}+\mu_{\mathrm{x}}$

## Eigenface Method

Eigenface method is the implementation of PCA over images. The Eigenface method eliminates variance resulting from non-face images to find a lower dimensional space for the representation of the face images.Take for instance a 2D situation where an input image is compared with a set of data base images to find the best match. And assume that all the images have the same resolution and are equivalently framed. Each pixel can be considered a variable thus having a very high dimensional problem which can be simplified by PCA.

In this method, the features of the studied images are obtained by the following;

- Convert each member of the training images into image vectors( $\Gamma$ ) by adding or appending each column one after the other .Each image vector may have a size, say Px1.
- Form Training set matrix containing all the image vectors :( $\left.\Gamma_{1}, \Gamma_{2}, \Gamma_{3, \ldots}, \Gamma_{\mathrm{M}}\right)$
- Calculate the mean vector of the entire image vector. That is arithmetic average of the training image vectors at each pixel point: $\left(\Psi=\frac{1}{M} \sum_{i=1}^{M} \Gamma_{\mathrm{i}}\right)$.
- Subtract mean vector from, every image vector in the a training image to look for the maximum deviation of each image from the mean image. $\Phi=\Gamma-\Psi$
- Form matrix with mean-centred image vectors. $\mathrm{A}=\left[\Phi_{1}, \Phi_{2}, \Phi_{3} \ldots \Phi_{\mathrm{M}}\right]$
- Calculate the covariance matrix of the images. $\mathrm{Z}=\mathrm{A} . \mathrm{A}^{\mathrm{T}}=\frac{1}{M} \sum_{i=1}^{M} \Phi_{\mathrm{i}} \Phi_{\mathrm{i}}$
- Obtain eigenvectors and their corresponding eigenvalues of the covariance matrix of the images.
- Eigenvectors are sorted in descending order by eigenvalues and eliminate eigenvectors with corresponding small eigenvalue.
- The eigenface space is obtained by applying the eigenvectors on the mean-centred images. $\omega=\mathrm{A} . v \mathrm{k}$,

Where $v k$ eigenvectors ofk=1,2,3...M'(M' number of selected eigenvectors. Weight matrix $\omega=\left[\omega_{1}, \omega_{2}, \omega_{3} \ldots \omega_{\mathrm{M}^{\prime}}\right]$

- Later, the training images are projected into the eigenface space $\Omega=\omega^{\prime}$. A
- Each image in the image space is transformed into eigenspace. In image space each image has a size of Px1 whereas in the eigenspace image has a size of M'x 1.The dimension is thus reduced as $\mathrm{M}^{\prime}<\mathrm{P}$.

### 2.6 Linear Discriminant Analysis (LDA)

## Introduction

Linear Discriminant Analysis is a popular classification technique developed by Roland Fisher. It is sometimes called Fisher Discriminant Analysis(FDA). The main objective of LDA is to separate samples of distinct groups. Essentially, it transforms data to a different space which optimally distinguishes classes.This was recognised and applied on face recognition by Belhumeur et al (1996).

The LDA basically finds a linear transformation in order that feature clusters are most separable after the transformation. And this can be achieved through scatter matrix analysis.

It maximizes the ratio of Between-classes scatter to Within-classes scatter in order to find the combination of features that separate best between classes. The Between-class (also known as extra-personal) scatter represents variations in appearance as a result of difference in identity. Within-class (intra-personal) scatter represents variations in appearance of the same individual due to different lighting and face expression. In other words, it finds the projection directions that on one hand maximize the distance between the face images of different classes and on the other hand minimize the distance between the face images of the same class. Consequently, images of the same class (or person) are grouped together whereas images of different class( or persons) are separated.

Take an instance, two sets of points in 2-dimensional space which are projected onto a single line. Depending on the direction of the line, the points can either be mixed together (as in the case of

Figure 2-6a) or separated (Figure 2-6b). LDA find $s$ the line that best separates the points.

Figure 2-6 (a) Points mixed when projected onto a line. (b) Points separated when projected onto another line.

Figure 2-7 shows good and bad class separation.

Figure 2-7(a) Good class separation. (b) Bad class separation.

The steps involved in LDA are as follow;

- Find the two scatter matrices referred to as the "between class" and "within class".
- finds a set of vectors $W_{\text {LDA }}$ such that Fisher Discriminant criterion is maximised.
$\mathrm{W}_{\mathrm{LDA}}=\operatorname{argmax}_{\mathrm{w}} \underline{\mathrm{W}}^{\mathrm{T}} \cdot \underline{\mathrm{S}_{\mathrm{B}}} \cdot \underline{\mathrm{W}}$

$$
\begin{equation*}
\mathrm{W}^{\mathrm{T}} \cdot \mathrm{~S}_{\mathrm{W}} \cdot \mathrm{~W} \tag{17}
\end{equation*}
$$

Where W is transformation matrix and $\mathrm{W}^{\mathrm{T}}$ is transpose matrix of W .
$\mathrm{S}_{\mathrm{B}}=\sum_{i=1}^{c} N_{\mathrm{i}}\left(\pi_{\mathrm{i}}-\mu\right) .\left(\pi_{\mathrm{i}}-\mu\right)^{\mathrm{T}}$
$\mathrm{Sw}=\sum_{i=1}^{c} \sum_{j=1}^{N i} \quad\left(\mathrm{x}_{\mathrm{j}}^{\mathrm{i}}-\pi\right) \cdot\left(\mathrm{x}_{\mathrm{j}}^{\mathrm{i}}-\pi\right) \mathrm{T}$

Where $\mathrm{N}_{\mathrm{i}}$ is the number of training samples in class i ,
c is the number of distinct images(classes), $\pi$ is the
class (group) mean of class i,
$\mu$ is overall mean, and $\mathrm{x}_{\mathrm{j}}{ }_{\mathrm{j}}$ represents the set of samples
belonging to class i.
$\mathrm{S}_{\mathrm{W}}=$ the scatter of features around the mean of each class and
$\mathrm{S}_{\mathrm{B}}=$ the scatter of features around the overall mean for all face classes.

The solution of the maximization problem is the solution of generalized eigensystem;
Sb. $V=\Lambda . S w . V$ $\qquad$

Where V is the eigenvector (Fisherface) matrix and $\Lambda$ are corresponding eigenvalues of the within class and between -class matrices.

This system can be easily solved by
$S^{-1} . \operatorname{Sb} . V=\Lambda . V$

However, this approach can produce the following problems;
i. This eigensystem does not have orthogonal eigenvectors because $\mathrm{S}_{\mathrm{W}}{ }^{-1}$. $\mathrm{S}_{\mathrm{B}}$ is, in general not symmetric.
ii. The matrices $S_{w}, S_{B}$ are usually too big iii. The number of training images available in the field of face recognition is undoubtedly significantly smaller than the images' dimension. This leads to the Within-class scatter matrix $S_{W}$ being singular and non-invertible, Jain (1991).

In attempt to overcome the problems enumerated above a modified LDA was recommended in Belhumeur et al (1997).The following were the recommendations;

- project all images into the PCA subspace. This is to reduce their dimensionality and consequently ensures that the matrix $\mathrm{S}_{\mathrm{W}}$ is invertible)
- perform LDA in the reduced space to produce transformation matrix W comprising of eigenvectors. At this point the eigenvectors can be referred to as fisherface or fisherface pattern. Struc and Pavesic (2008), Delac et al (2005).

## Algorithmic Description of LDA

To begin with, all images are projected into the PCA subspace instead of using the pixel values of the images. The eigenface projection of PCA transformation is initially applied in the Subspace LDA method. Equations 11-16 referred.

- Convert each member of the training images into image vectors ( $\Gamma$ ) by adding or appending each column one after the other.
- Form Training set matrix containing all the image vectors : $\left(\Gamma_{1}, \Gamma_{2}, \Gamma_{3, \ldots}, \Gamma_{\mathrm{M}}\right) \square$ Calculate the mean vector of the entire image vector. $\left(\Psi=\frac{1}{M} \sum_{i=1}^{M} \Gamma_{\mathrm{i}}\right)$
- Subtract mean vector from, every image vector in the a training image. $\Phi=\Gamma-\Psi$
- Form matrix with mean-centred image vectors. $\mathrm{A}=\left[\Phi_{1}, \Phi_{2}, \Phi_{3} \ldots \mathrm{Q}_{\mathrm{M}}\right]$
- Calculate the covariance matrix of the images. $\mathrm{Z}=\mathrm{A} \cdot \mathrm{A}^{\mathrm{T}}=\frac{1}{M} \sum_{i=1}^{M} \Phi_{\mathrm{i}} \Phi_{\mathrm{i}}$
- Obtain eigenvectors and their corresponding eigenvalues of the covariance matrix of all the images.
- Sort eigenvectors in descending order by eigenvalues and eliminate those with corresponding small eigenvalues.
- Apply the eigenvectors on the mean-centred image vectors to obtain eigenface space. $\omega=A . v k$, where $v k$ eigenvectors of $k=1,2,3 \ldots M^{\prime}\left(M^{\prime}\right.$ number of selected eigenvectors.

Weight matrix $\omega=\left[\omega_{1}, \omega_{2}, \omega_{3} \ldots . \omega_{\mathrm{M}}{ }^{\prime}\right]$

- Later, the training images are projected into the eigenface space. $\Omega=\omega^{\prime}$. A

Use the eigenspace to compute the between-class and within-class scatter matrices

- Compute the arithmetic average of the eigenface projected training image vectors corresponding to the same individual class. $\mathrm{m}_{\mathrm{i}}=\frac{1}{q i} \sum_{k=1}^{q i} \Omega_{\mathrm{k}}, q^{i}=1,2, \ldots \mathrm{C}$ and size of
each eigenface class mean is ( $\mathrm{M}^{\prime} \times 1$ ).
- Compute the arithmetic average of all the eigenface projected training image vectors. $\mathrm{m}^{0}=\frac{1}{M} \sum_{k=1}^{M \prime} \Omega_{\mathrm{k}}$
- Compute the Within Class Scatter Matrix: - It represents the average scattering of the projection matrix $\Omega$ in the eigenface space of different individuals $C_{i}$ around their respective class means $\mathrm{m}_{\mathrm{i}}$.
- Compute the Between-Class Scatter Matrix: - It also represents the scatter of each projection classes mean $m_{i}$ around the overall mean vector $m_{0}$.
- Find the projection say W which maximizes between-class scatter and minimizes withinclass scatter. W can be obtained by solving the generalized eigenvalue problem; $\mathrm{Sb} W=\mathrm{S} w W \lambda_{\mathrm{w}}$,

Here too the vectors W are selected based on their corresponding eigenvalues, thus eliminating the vectors with smallest eigenvalues. This implies that the selected number of eigenvectors (fisherfaces), F will be less than the number of vectors in the eigenspace ( $\mathrm{M}^{\prime}$ ) that LDA started with.

- Project the eigenface projections of the training image vectors to the fisherface space by the dot product of optimum projection, W and eigenface projection matrix, $\Omega$. $\mathrm{g}(\Omega)=\mathrm{W}^{\mathrm{T}} . \Omega$, It is of size ( $\mathrm{F} \times \mathrm{M}^{\prime}$ ). $\qquad$

### 2.7 CLASSIFICATION (RECOGNITION)

Classification: -It is the problem of identifying which set of categories a new observation belongs to, based on a training set of data containing observation whose category membership is known. The distance measure between data points is an important component of a classification algorithm.

The most popular distance measures used are as follow:
A. Euclidean distance function

In mathematics, the Euclidean distance or Euclidean metric is the "ordinary" distance between two points. This is calculated by the Pythagorean formula.

## B. City Block distance function

The City Block distance (also referred to as Manhattan distance)between two items is the sum of the differences of their corresponding components.

The distance between two points, $a$ and $b$, with $k$ dimensions is calculated as:

$$
\begin{equation*}
\sum_{j=1}^{k}\left|a_{j}-b_{j}\right| \tag{25}
\end{equation*}
$$

It is always greater than or equal to zero. If the measurement is zero then they are identical points whereas high measurement will indicate little similarity

## C. Cosine Similarity

The Cosine similarity between two vectors is a measure that calculates the cosine of the angle between them. This metric is a measurement of orientation and not magnitude .It can be seen as a comparison between vectors on a normalized space since it does not only take into consideration the magnitude of each vector, but the angle between them. It is solved by finding the dot product for the angles between the vectors. (i.e. $\cos \theta$ ):

Cosine Similarity generates a metric using angles to show the relationship between two vectors, as can be seen in figure 2-8:

The Cosine Similarity values for different vectors are 1 (same direction), 0 ( 90 degrees.), -1 (opposite directions). Figure28 Cosine Similarity metrics

Given two vectors of attributes, $A$ and $B$, the cosine similarity, $\cos (\theta)$, is represented using a dot product and magnitude as

$$
\begin{equation*}
\text { similarity }=\cos (\theta)=\frac{A \cdot B}{\|A\|\|B\|}=\frac{\sum_{i=1}^{n} A_{i} \times B_{i}}{\sqrt{\sum_{i=1}^{n}\left(A_{i}\right)^{2} \times \sqrt{\sum_{i=1}^{n}\left(B_{i}\right)^{2}}} .} \tag{26}
\end{equation*}
$$

The result ranges between -1 and 1 . The -1 means the vectors are exactly opposite whereas 1 is exactly the same. The result 0 indicates orthogonality (de-correlation)whiles the in-between values means intermediate similarity or dissimilarity.

With regard to face recognition, classification is employed to perform similarity measure. This measure defines the distance or angle between the projected Test image and each image in projection matrix depending on the similarity measure used.

Once the face images have been projected into the eigenspace or fisherface, the similarity between any pair of face images can be calculated by finding distance or angle between their corresponding
feature vectors. The smaller the distance(in respect of Euclidean and city block distance measures)or angle (in respect of Cosine Similarity) between the features, the more similar the faces.

Algorithmic Description of Classification

- Convert the test (probe) image into a single column vector, $\Gamma_{\mathrm{T}}$
- Substract mean image vector from test image. $\Phi_{\mathrm{T}}=\Gamma_{\mathrm{T}}-\Psi$
- The mean-centered image is projected over eigenspaces / fisherfaces. $\Omega_{\mathrm{T}=\omega^{\prime} . \Phi_{\mathrm{T}}}$
- Compute the similarity distance metrics (Euclidean distance, city block and cosine) using the projected vector of the test image and that of the training set.
- The projected image vector of the training set with the least distance metric (in the case of Euclidean distance, city block) or maximum cosine value ( in the case of cosine similarity measure) compare to test image becomes the equivalent image of the tested image.

## CHAPTER THREE

## METHODOLOGY

The aim of this study was to perform the comparative analysis of PCA and LDA as applied on face recognition. First of all the algorithms of the PCA and LDA were implemented and then evaluated their performances under various parameters.

In this thesis, a framework of facial biometric was designed based on the two feature extraction subspace methods studied.. Both PCA and LDA features were presented to the same similarity measures separately such as Euclidean distance, City Block and Cosine Distance measurement. The algorithms were tested with standard face database which were AT and T Database and Indian Face Database.

The framework had four phases viz: Data Formation Phase, Training Phase, Recognition Phase and Performance Phase.

### 3.1 DATA FORMATION PHASE

For consistency with other studies and the need for uniform benchmark database, this study used two different standard set of face images from AT\& T Database which had been collected by AT \& T Laboratories at Cambrigde and Indian Face Database.

AT \& T Database contained 400 images with 10 different images of 40 distinct subjects (persons). The images were of portable gray map (.pgm) format. They varied in terms of lighting, facial expressions including open/closed eyes, facial details such as glass/without glasses and different time of snapping pictures. All the images were taken against a dark homogeneous background with the subjects in an upright, frontal position. The Figure3-1 is an example of AT \& T face images.

Figure 3-1;Sample images in AT \& T Database

The Indian Face Database (IFD) contained 429 male images and 242 female images from Indian Institute of Technology, Kanpur Campus. The male group had averagely 11 different images of 39 subjects (persons) whereas female contained 11 different images of 22 subjects (persons).IFD contained images of 61 distinct subjects with eleven different poses for each individual. However, in the study 600 images were used. The images had bright homogeneous background and the subjects were in an upright, frontal left, looking right, looking up, looking up towards left, looking up towards right, looking down. In addition to the variation in pose, images with four emotions neutral, smile, laughter, sad/disgust - were also included for every individual.The images were of joint photographic expert group (.jpg or .jpeg) format. Figure 3-2a,b,c d are samples of original Indian Face Images.

Figure. 3-2a
Figure 3-2c

Figure 3-2b
Figure 3-2d
Having obtained images to test the algorithms, the images were pre-processed for effective test.
The pre-processing was done to perform image size conversions (i.e from original of $640 \times 480$
pixels to $60 \times 50$ pixels) and enhancements on face images. Again, as part of the pre-processing activities, the dynamic range of face images were modified (histogram equalization) in order to improve face recognition performance. That is, image pixel values were histogram equalized to the range of values from 0 to 255 .

For example the original Indian face images (figures 3-2a , 3-2b) which were coloured but not cropped were pre-processed as follows;
a. Changed the images to grey(as can be seen in figure3-3a\&3-3b).
b. Cropped them to 300 (height) $\times 280$ (width)to eliminate as much background as possible.(as shown in figure3-3a \&3-3b).
c. Resized to $60 \times 50$ pixels (as shown figure $3-4 \mathrm{a}$ and $3-4 \mathrm{~b}$ ).
d. Histogram equalised (as shown in figure 3-4a and 3-4b).

The figures 3-3a and 3-3b are samples of the images grey scaled and cropped

Figure3-3a

Figure 3-3b
The figures $3-4 \mathrm{a}$ and $3-4 \mathrm{~b}$ are samples of the images resized and histogram equalised

Figure3-4a

As pre-processing steps, the file format of AT\& T face images (.pgm) were converted into .jpg for uniformity. The images which were already cropped and in greyscale (but not coloured) were resized to $60 \times 50$ pixels .Again, they were histogram equalized as shown in Figure 3-5a, b, c.

The codes in appendix A was used to perform it.

Figure 3-5 a

Figure 3-5b
Figure 3-5c
Figure a=Original Images (112x92 pixels)
Figure b $=$ Resized images (60x50 pixels) Figure
$c=$ Histogram equalised Images

The pre-processed images were stored into Training database and Probe database.
The study categorised the Training and Probe database into three separate datasets for each of the standard database used namely Dataset1 (TrainDatabase1 and ProbeDatabase1), Dataset2
(TrainDatabase2 and ProbeDatabase2), and Dataset 3 (TrainDatabase3and ProbeDatabase3). The TrainDatabases 1,2 and 3 contained three, five and ten images per person(class) respectively whereas the ProbeDatabases 1,2 and 3 contained one selected image per person from their respective TrainDatabases. Hence the datasets which were formed from AT \&T Database and Indian Database were as follows;

## AT \& T DATABASE

DATASETS NO. OF IMAGES

Dataset 1:

| TrainDatabase1 | $120(3$ images per person $)$ |
| :--- | :--- |
| ProbeDatabase1 | 40 |

Dataset 2:

INDIAN FACE DATABASE
DATASETS NO. OF IMAGES
Dataset 1:
TrainDatabase 1
180 (3 images per person)
ProbeDatabase 1
Dataset 2:
TrainDatabase2
ProbeDatabase2
50

300 (5 images per person)
50

Dataset 3:
TrainDatabase3
600(10 images per person)
ProbeDatabase3
50

### 3.2 TRAINING PHASE

In this phase the algorithms of PCA and LDA were employed. After adding face images to the initially empty training databases, the PCA or LDA algorithm was initialized by feeding it a set of training image of faces. The resized images ( $60 \times 50$ pixels) were each reshaped into 1 D column vector ( 3000 x 1 ) by concatenating each column pixel of each 2 D image one to another. These 1 D vectors were put together into 2 D matrix "T" called the Training set .The Training set, containing all training image vectors, was used to define the face space. Matlab functions called EigenfaceCore in the case of PCA algorithm and Fisherface Core for LDA algorithm were created to extract the intrinsic features of the images.

The EigenfaceCore performed the following activities;

- Mean face calculation (arithmetic average of the training image vectors at each pixel point),
- difference matrix / mean centred (where mean face vector was subtracted from each training vector),
- Covariance matrix (dot product of the transpose of difference matrix and the difference matrix itself). Then used eigfunction in MATlAB to produce eigenvectors and their corresponding eigenvalues. These were sorted eliminating vectors with less than or equal to zero eigenvalues.
- Eigenface space (dot product of the eigenvector of the covariance matrix and the difference matrix )
- Projection matrix (The matrix of mean centred images were then projected onto the eigenfacespace). That is, the dot product of the eigenfaces and the difference matrix. The output of the preceding activity served as input for the activity that followed.

The output of EigenfaceCorefunction (the mean vector of the training database, matrix of mean centred image vectors and Eigen vectors of the covariance matrix of the trainingdatabase became the input for recognition function. The sample patterns or images of the output are shown in figures 3-6, 3-7, and 3-8.

Figure 3-8 Samples of Eigenfaces(eigen pattern)

## The Fisherface Core

The eigenface projections of PCA transformation were used in the Subspace LDA method instead of using the pixel values of the images.

- At first, centred images were mapped onto a (P-C) linear subspace as was the case in EigenfaceCore. Here it was P-C linear subspace in that the eigenvectors were sorted by their corresponding eigenvalues and those with small eigenvalues were eliminated leaving up to (P-C ) number of eigenvectors to form the eigenspace.
- The projected images were then projected onto a (C-1) linear subspace, so that images of the same class (or person) move closer together and images of difference classes move further apart.
- Calculated the mean of each class in the eigenspace (projection class mean) $\circ$ Calculated the total mean in the eigenspace $\circ$ Performed the within scatter matrix by subtracting the eigenfaces class mean from each of the projected images of PCA within a class. Then did a dot product of the result and its transpose.
- Performed the between scatter matrix by subtracting the eigenfaces mean(overall mean) from projection class mean and did dot product of the result and its transpose.
- Calculated fisher discriminant basis (linear fisher space) by maximising the between class while minimising the within class. That was done by using eig function in Matlab which produced eigenvectors and their corresponding eigenvalues.
- The eigenvectors with zero eigen values were eliminated leaving C-1 number of eigenvectors to form a matrix.
- Projected the projected images of PCA onto the linear fisher subspace by doing a dot product of the transpose of the fisherface (matrix) and the projected images of PCA.
- These activities produced four outputs(the Mean of the Training set, Eigen vectors of the covariance matrix of the training database, Fisherface space and projected fisherface) which were used in recognition phase as input. Figures 3-9,3-10, and 3-11 represent sample patterns or images of some the outputs.

Figure 3-9Mean image (parttern) of the training set

Figure 3-10sample of Eigenface of the covariance of the training set

Figure 3-11Fisherface(parttern)

### 3.3 RECOGNITION (CLASSIFICATION) PHASE

At this stage, the algorithm performed identification of unknown image (test/probe image). The test (probe) image was also projected over eigenface space (in the case of PCA) or fisherface space (in the case of LDA) like that of training images in the training phase.

- The test image with same size of 60 x 50 pixels was reshaped into column vector
- It's column vector was mean subtracted and projected onto the eigenface space or fisherface space
- The projected test image was then classified (recognized). That is, the distance between the projected test image and all the training images in eigenface space or fisherface space using any of the three distance or similarity measures (Euclidean distance, City Block, Cosine). Recognition function was created in MATLAB to compare test image and all the images in the training set to obtain equivalent image in the training database. The figure 3-12 and figure 3-13 are the illustrations of the result of the recognition phase. They showed the time it took the projection-metric combination algorithm being used to recognise a face or identify a match of the input image in the database. They also showed the similarity measure or metric used and the filename of the equivalent image.

Figure 3-12 : A sample of results of Indian Face tested

Figure3-13: A sample of results of AT\& T face image tested.

### 3.4 PERFORMANCE EVALUATION

At this stage the performance of all projection-metric combined algorithms were assessed to ascertain the most efficient.

The analysis was done based on the following parameters:-

- Accuracy(Recognition rate) $=\underline{\text { Number of correctly matched images } \times 100}$

Total number of probe image

- Execution time $=$ time taken (in seconds) for execution of algorithm
- Average Execution Time of an algorithm=Sum of Execution Time/ Total number of probe image
- Effect of varying number of training image, and number of images of person (class) which will include the generalization ability of the projection-metric combination.

The face recognition experiments were done with six different projection-metric algorithms viz; PCA-Euclidean distance metric, PCA-City Block metric, PCA- Cosine metric, LDA-Euclidean distance, LDA-City Block and LDA-Cosine metric. Each of the algorithms was executed using the three separate datasets of eachof the face Database. Thus, 18experiments (scenarios) were performed with each of the two face database;

- PCA-Euclidean distance metric using dataset 1
- PCA-Euclidean distance metric using dataset2
- PCA-Euclidean distance metric using dataset3
- PCA-City Block metric using dataset1
- PCA-City Block metric using dataset2
- PCA-City Block metric using dataset 3
- PCA- Cosine metric using dataset 1
- PCA- Cosine metric using dataset 2
- PCA- Cosine metric using dataset 3
- LDA-Euclidean distance metric using dataset 1
- LDA-Euclidean distance metric using dataset2
- LDA-Euclidean distance metric using dataset3
- LDA-City Block metric using dataset 1
- LDA-City Block metric using dataset2
- LDA-City Block metric using dataset3
- LDA- Cosine metric using dataset 1
- LDA- Cosine metric using dataset 2
- LDA- Cosine metric using dataset 3

The purpose was to observe the behaviour of each projection-metric as the sample size changes.
The results of the experiments (scenarios) indicated in the tables 3-1,3-2,3-3,3-4,3-5,3-6,3-7,38,3-9,3-10,3-11, and 3-12 showed the time taken for each algorithm to recognise a probe(input) image and also indicated whether there was a true match or not. Each of the tables had three sub- tables showing the results when the datasets 1 , 2, and 3 were used .Tables 3-1 to 3-6 contained results when AT\& T Database was used whereas Tables 3-7 to 3-12 had outcome of Indian Face Database.

## KNUST

## CHAPTER FOUR

## ANALYSIS OF RESULTS

The results from all the experiments indicated $100 \%$ accurate recognitionrate as illustrated in Tables 4-1 and 4-2regardless of increase in number of images per class (person) and its corresponding increase in the number of images in all the training datasets. Conversely, observing the result from the highest image per person (class) with its corresponding highest number of images in the training database considered and reducing them to the lowest in all the projectionmetric combination experimented the same accurate recognition rate was obtained.

Thus, the generalisation abilities of all the projection-metric combinations (PCA-M1, PCA-M2, PCA-M3, LDA-M1, LDA-M2, and LDA-M3) were excellent.

A=Number of Correctly Matched Images
$B=$ Number of Probe/Test Images, $C=$ Recognition Rate $=A / B * 100 \%$

Though IFD had images where each subject or class was portrayed with highly varying orientation angles than AT \& T images, it did not have any effect on the recognition rate of any of the techniques used .Obviously, the results of all the projection-metric combination considered on the two Databases had $100 \%$ accurate recognition.

In all the algorithms executed with AT \& T Database, the Table 4-3 showed that average execution time increased as the image size per person in the training database increased. Take an instance. PCA-M1 (PCA combined with Euclidean distance Metric) had average execution time of 3.2
seconds with dataset1 (3 images per person in the training database), 4.44 seconds with dataset 2 (5 images per person in the training database) and 10.62 seconds with dataset3 (10 images per person in the training database). LDA-M2 (LDA combined with City Block Metric) had average execution time of 2.59 seconds with dataset $1,3.52$ seconds with dataset 2 and 8.69 seconds with dataset 3 . This behaviour can easily be noticed in the figure 4-1.

However, from the same table and chart, LDA appeared to have average execution time increased but lower than PCA in all the projection-metric considered as the image size per person increased.

TABLE 4-3: Average Execution Time (in seconds) For Projection-Metric Algorithms with
AT\& T Database

| ALGORITHMS | AVERAGE EXECUTION TIME(SECONDS) |  |  |
| :--- | ---: | ---: | ---: |
| Projection-Metric | Dataset 1 | Dataset 2 | Dataset 3 |
| PCA-M1 | 3.20 | 4.44 | 10.62 |
| PCA-M2 | 3.20 | 4.52 | 10.89 |
| PCA-M3 | 3.07 | 4.48 | 10.71 |
| LDA-M1 | 2.59 | 3.52 | 8.69 |
| LDA-M2 | 2.58 | 3.44 | 9.28 |
| LDA-M3 | 2.57 | 3.56 | 8.57 |

M1-Euclidean Distance Metric M2-City Block Metric M3-Cosine Metric
Figure 4-1:Average Execution Time (in seconds) For Projection-Metric Algorithms with AT \& T Database

Similarly, the table 4-4 showed increase in average execution time for all the projection-metric algorithms as the image size per person increased. For example, PCA with Euclidean distance metric (PCA-M1) had 5.54 seconds with dataset1, 8.42 seconds with dataset 2 and 23.73 seconds with dataset 3 . The figure 4-2 depicted the behaviour in the table 4-4.

However, the difference between the result in Table 4-3 and 4-4 was that for all the algorithms, the average execution times for Table 4-4 were more than that of Table 4-3 due to the fact that the total number of images in the training database of each of the datasets were more in the case of Indian Face Database (Dataset1: 180 images, Dataset2: 300, Dataset3: 600 images) than AT \&

T Database (Dataset 1: 120 images, Dataset2: 200 images, Dataset 3 : 300 images) employed. The analysis in the two tables 4-3 and 4-4 had shown the effect of varying the image size per person and consequently the size of images in the training database. That is, both PCA and LDA proved
that time of execution of each algorithm averagely increases as the size of the training database increases.

TABLE 4-4: Average Execution Time (in seconds) For Projection-Metric Algorithms with
Indian Face Database

|  | AVERAGE EXECUTION TIME <br> ALGORITHM |  |  |
| :--- | ---: | ---: | ---: |
| SECONDS) |  |  |  |
| Projection-Metric | Dataset 1 | Dataset 2 | Dataset 3 |
| PCA-M1 | 5.54 | 8.42 | 23.73 |
| PCA-M2 | 5.12 | 8.32 | 23.62 |
| PCA-M3 | 4.96 | 8.12 | 23.4 |
| LDA-M1 | 3.99 | 6.31 | 22.85 |
| LDA-M2 | 3.81 | 6.11 | 23 |
| LDA-M3 | 3.77 | 5.98 | 22.69 |

M1-Euclidean Distance Metric M2-City Block Metric M3-Cosine Metric

Figure 4-2: Average Execution (in seconds) for Projection-Metric Algorithms with Indian Face Database

Again, it is important to note that the average time taken for LDAs to recognise a face was better than that of the PCAs in all the training image size of both database used as illustrated in Table 43 and 4-4 as well as the figures 4-1,4-2. Therefore it can be concluded that LDA outperformed the PCA.

In an attempt to specifically point out which projection-metric combination is more efficient and appropriate for what situation, rankings for projection-metrics (in terms of their average time taken to recognize a face when applied on a specific dataset of a particular database)were done (as illustrated in Table4-5 and 4-6).The Table 4-5 showed that with AT\& T database, PCA-M1 and LDA-M3 ranked best among the PCA and LDA methods respectively. However, comparing the average execution time of both PCA-M1 and LDA-M3 for dataset3(with the largest image data size of 400 images) it turned out that LDA-M3 ( 8.57 seconds) was better than PCAM1 (10.62

## seconds).

Similarly, with the IFD PCA-M3 and LDA-M3 also ranked the best among the PCA and LDA methods respectively. Again, comparing the average execution time of both PCA-M3 and LDAM3 for dataset3 (with the largest image data size of 600 images) LDA-M3 ( 22.69 seconds) was preferred to PCA-M3 for dataset3 (23.40 seconds).Obviously, the LDA-M3 was the preferred choice in all cases. This became clear when the overall ranking was considered as shown in Table 4-6 that LDA-M3 is the most efficient among all the projection-metric algorithms executed with AT\& T Database and IFD. It also meant that LDA-M3 was capable of withstanding large training database of face images than the other projection-metric algorithms. On the other hand, PCA-M1 could not stand large database hence it would be improper to recommend it for Voter registration and Verification which usually has large database.

The above results also showed that the increase in size of image per person and corresponding increase in size of the training database had severe impact on the PCA compare to LDA as far as
performances (in terms of time taken) of the algorithms were concerned. That is to say, in all cases LDA algorithms were executed much faster than that of PCA. Hence LDA outperformed PCA in respect of efficiency (in terms time taken to execute algorithm).

| LDA-M3 | 1 | 3 | 1 | 1 | 1 | 1 | 1.33 |

## CHAPTER FIVE

## CONCLUSION,RECOMMENDATION AND FUTURE WORK

Empirical assessment was made of the two popular appearance based techniques of face recognition (PCA and LDA). The publicly available databases AT \& T and Indian Face image database were used to implement algorithms of the two techniques and consequently evaluated. The research considered the effect on accurate recognition and the computational cost (in terms of time of execution of algorithm) of implementing the two techniques indicated above combined with three similarity measure as image database size changes. The study showed that regardless of the size of image per person and the training database size the accuracy of the techniques was not compromised. The generalization abilities of all the projection-metric combination considered were excellent. The study demonstrated that there is lower computational cost in all projectionmetric algorithms of the LDA techniques than that of PCA. The LDA-Cosine Metric was preferred to other projection-metrics studied since with the larger data size it turned out to be the most efficient. PCA-Euclidean distance metric performed worse in terms of average time taken and appear not to have the capability to withstand larger training database.

As far as recognition rate is concerned the study agrees with Delac et al (2006) which stated that "the performance of the appearance based methods is heavily dependent on the employed distance measure and that with the right combination of appearance based method and distance no claim regarding the superiority of any of the techniques i.e., PCA, LDA can be made".

## RECOMMENDATION

Obviously, LDA especially LDA-Cosine metric will be much more preferred in situation where large number of people are involved in the recognition process and little amount of time is required for an individual to be recognised by the system. Voter Registration and Verification Exercise, Customs and Immigration activities are few examples

In organisations where there is not much traffic on their security access control systems any of the projection-metric methods can be adopted since in terms of accuracy (recognition rate) none of the methods implemented is superior to the other. However, where the access control systems will have to record time of entry of staff (especially reporting time) then LDA-cosine metric method is most appropriate compare to the other five methods implemented.

## FUTURE WORK

Future research should focus on employing more than three similarity measures to combine with the LDA and PCA and expanding the image data size beyond 600 images to determine which projection-metric methods is most efficient and can withstand larger training database.
